ABSTRACT

Background: Leprosy is an ancient chronic infection in the skin and peripheral nerves caused by *Mycobacterium leprae*. The development of leprosy depends on genetic background and the immune status of the host. However, there is no systematic view focusing on the biological pathways, interaction networks and overall expression pattern of leprosy-related immune and genetic factors.

Objectives: To identify the hub genes in the center of leprosy genetic network and to provide an insight into immune and genetic factors contributing to leprosy.

Methods: We retrieved all reported leprosy-related genes and performed integrative analyses covering gene expression profiling, pathway analysis, protein–protein interaction network, and evolutionary analyses.

Results: A list of 123 differentially expressed leprosy related genes, which were enriched in activation and regulation of immune response, was obtained in our analyses. Cross-disorder analysis showed that the list of leprosy susceptibility genes was largely shared by typical autoimmune diseases such as lupus erythematosus and arthritis, suggesting that similar pathways might be affected in leprosy and autoimmune diseases. Protein–protein interaction (PPI) and positive selection analyses revealed a co-evolution network of leprosy risk genes.

Conclusions: Our analyses showed that leprosy associated genes constituted a co-evolution network and might undergo positive selection driven by *M. leprae*. We suggested that leprosy may be a kind of autoimmune disease and the development of leprosy is a matter of defect or over-activation of body immunity.

1. Introduction

Leprosy is an ancient chronic infectious disease caused by *Mycobacterium leprae* and causes a variety of disabilities [1]. Epidemiological survey have found that less than 10% of people in contact with *M. leprae* would develop the disease and the current prevalence rate was estimated as 0.31–0.32 per 10,000 population [2–4]. In the long evolutionary process of interaction with the host,

M. leprae lost about 50% coding genes in its genome, making it a stringent host-dependent intracellular parasite [5,6]. Development of leprosy is determined by the host immune status and genetic background, and there are little differences among different *M. leprae* strains [2,7]. Genomes or genetic susceptibility factors and immune response of those susceptible individuals may be shaped by selection pressure driven by this ancient pathogen [8].

Leprosy can be classified into multibacillary (MB) and paucibacillary (PB) leprosy based on the clinical manifestations and the number of skin lesions according to the World Health Organization (WHO) guidelines [9,10]. Leprosy can also be classified into five subtypes, including two polar forms of leprosy (lepromatous leprosy [LL, belongs to MB] and tuberculoid leprosy [TT, belongs to PB]) and three immunologically unstable borderline forms (borderline tuberculoid leprosy [BT], mid-borderline leprosy

[BB], borderline lepromatous leprosy [BL]) [10]. The immune responses of patients with leprosy include type I and type II reactions [11–14]. Type I leprosy reaction is mainly characterized by up-regulation of Th1 type T cells expressing IL-2 and IFN- γ , whereas type II reaction is mainly up-regulated by Th2 type T cells and increases proinflammatory cytokines such as TNF- α , IL-6, and IL-1 β . The TT is characterized by a strong Th1 cellular immunity with type I reaction, whereas the LL is caused by the defect of cellular immunity with complicated type II reactions or erythema nodosum leprosum reactions [11–14]. However, it is unclear whether there is leprosy-specific immune profile that would distinguish it from other infectious or immune diseases.

Genetic linkage analysis [15], association analyses [16–21] and genome-wide association study (GWAS) [22,23] have reported numerous leprosy susceptibility genes, most of which are involved in the immune system. Pattern recognition receptors (PRRs) play a key role in pathogen recognition and signal transduction [24]. Genetic polymorphisms of these genes, including Toll-like receptors outside the cell membrane and intracellular NOD-like receptors, have been widely reported to be associated with leprosy [18,25]. Genetic polymorphisms of cytokines, such as TNF- α [26], INF- γ [19], interleukin (ILs) [27], and human leukocyte antigen (HLA) [28,29] that were involved in type I and type II reactions have been identified to be related to leprosy susceptibility. Although the associations of several top genes such as *IL10*, *TNF*, *NOD2*, *PARK2*, Toll-like receptors (e.g., *TLR1* and *TLR4*), and HLA alleles (e.g., *HLA-DRB1*) with leprosy have been well replicated, a number of leprosy associated genes were analyzed in different populations with insufficient replications (cf. <https://phgkb.cdc.gov/HuGENavigator/startPagePhenoPedia.do>). There were successful attempts using animal experiments with *M. leprae* strains to study the pathobiology of leprosy [30], yet functional investigation of

potential leprosy causal genes is still a challenge. What's more, reported genetic association studies had paid limited attention to the gene expression pattern of leprosy susceptibility genes.

Hitherto, there is no report for integrative analyses of leprosy. In this study, we collected all reported leprosy-related genes and performed integrative analyses, to fully characterize host immune response and genetic background that influence the development and susceptibility to leprosy.

2. Materials and methods

2.1. Research strategy

We took the following strategies in our integrative analyses (Fig. 1): First, we retrieved all leprosy-associated genes from published sources as a preliminary gene set. Second, the preliminary gene set was checked and filtered with gene expression profiling. Third, Gene Ontology (GO) enrichment analysis [31] for terms of Biological Process (BP), Cellular Component (CC), Molecular Function (MF) was conducted for the filtered gene set. Fourth, cross-disorder analysis was performed for the gene set to identify shared genetic factors between typical infectious and immune diseases. Fifth, protein–protein interaction and co-expression network analysis [32] was performed for the genes in the gene set [33–35]. Finally, the leprosy susceptibility genes were analyzed for positive selection among populations by using an integrated method CMS (Composite of Multiple Signals) [36].

2.2. Gene set compilation and assignment

Four public data sources were employed to compile the complete gene list of all reported leprosy associated genes: (1)

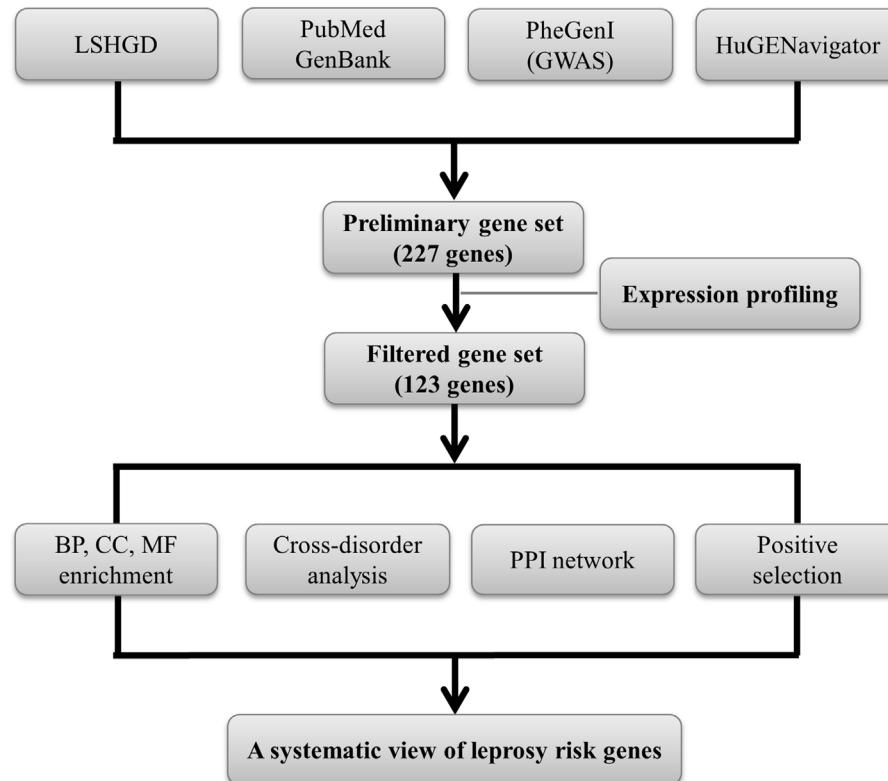

Fig. 1. Study design of the integrative analyses.

We retrieved all leprosy-related genes from published sources. The preliminary gene set were checked and filtered by referring to gene expression profiling. The filtered gene set was used for Gene Ontology (GO) enrichment analysis for Biological Process (BP), Cellular Component (CC), and Molecular Function (MF), cross-disorder analysis [31], protein–protein interaction and co-expression network analysis [35], and positive selection analysis.

LSHGD (<http://info.vit.ac.in/leprosy/leprosy.htm>) [37], a database for human leprosy susceptible genes developed in 2012; (2) the Human Genome Epidemiology (HuGE) Navigator (<https://phgkb.cdc.gov/HuGENavigator/startPagePhenoPedia.do>) [38]; (3) The Phenotype–Genotype Integrator (PheGenI, <http://www.ncbi.nlm.nih.gov/gap/phegeni>), which provides the NHGRI genome-wide association study (GWAS) catalog data; (4) PubMed and/or GenBank. For those reports published before September 2012, we directly obtained the leprosy associated gene list ($N=47$) from LSHGD [37]. We searched PubMed and/or GenBank using “leprosy”, “association”, “gene”, and “genetic variants” as keywords and we retrieved 98 genes reported in leprosy genetic association studies. For the PheGenI; GWAS data [22] with a P -value $< 5.0 \times 10^{-5}$ were retrieved and we got 107 leprosy-associated SNPs from 39 genes. From the HuGENavigator; we compiled 224 leprosy-related genes. All genes from these four sources were merged as the preliminary gene set; which contains 227 genes

after the exclusion of the overlapping genes. Hitherto; there is limited number of risk genes reported in leprosy compared with other common diseases. Therefore; we kept all reported leprosy-related genes in the gene set; ignoring the sample size and allele frequency in the original study; as the enrichment analysis requires a relatively larger gene number. We used gene expression change as the criterion to filter the gene list in following analyses (Fig. 1).

2.3. Gene expression profiling

Expression data was retrieved from the Gene Expression Omnibus (GEO, <http://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE74481>) [39]. In this microarray data, 16487 genes were analyzed for the leprosy skin lesions from 66 patients including 20 PB (10 TT + 10 BT), 24 MB (10 BB + 10 BL + 4 LL), 14 type I reaction (R1), and 10 type II reaction (R2) patients, and normal skin biopsies

from 9 healthy individuals. We screened mRNA expression data of the genes in the preliminary gene set ($N=227$) and retrieved the top differently expressed gene with a cut-off P -value $<5.0 \times 10^{-6}$ (experiment-wide significance) in PB and MB patients.

2.4. Enrichment analysis

GO enrichment analysis using terms of Biological Process (BP), Cellular Component (CC), and Molecular Function (MF) [31] was performed for the leprosy susceptibility gene set. We used the Database for Annotation, Visualization and Integrated Discovery v6.7 (DAVID, <http://david.abcc.ncifcrf.gov/>) [31], which provides a comprehensive set of functional annotation tools, to perform the enrichment analysis and to infer potential biological meanings behind our list of genes.

2.5. Protein–protein interaction (PPI) and co-expression network analysis

PPI network analysis was performed by a biological network integrator: the GeneMANIA prediction server (<http://www.genemania.org/>), which contains physical protein–protein interaction, pathway analysis, and co-expression analysis [33–35]. The list of leprosy susceptibility genes was set as the input seed. Both direct and indirect interaction networks were included in our analysis.

<http://www.genemania.org/>), which contains physical protein–protein interaction, pathway analysis, and co-expression analysis [33–35]. The list of leprosy susceptibility genes was set as the input seed. Both direct and indirect interaction networks were included in our analysis.

2.6. Cross-disorder analysis

To clarify whether the leprosy associated genes involved in immune response are leprosy-specific or common for other infectious and/or immune diseases, we performed a cross-disorder analysis. The list of leprosy associated genes were screened in the disease association dataset (Genetic Association DB Disease: <http://geneticassociationdb.nih.gov/>) using DAVID [31].

2.7. Positive selection analysis

We used the positive selection data produced by an integrated method CMS [36], a tool for identifying regions that are under positive selection in the genome using whole-genome sequencing data from the 1000 Genomes project (www.1000genomes.org/) [40]. It generates a composite score based on three distinct

^a The percentage is defined by the number of gene count for each terms divided by 123 leprosy associated genes.

signatures of selection: long-range haplotypes, differentiated alleles, and high frequency derived alleles. By combining several, nearly-independent signals, CMS detects signals of positive selection at a much higher resolution than the conventional tests, often at the level of single genes. We searched the CMS Viewer tool (<http://www.broadinstitute.org/mpg/cmsviewer/>) [36] to explore positive selection in three populations (European [CEU], African [YRI], and East Asian [CHB + JPT]) for regions of interest (here refer to the leprosy associated genes). A CMS score of one site greater than 3.0 (FDR < 0.05) was set as positive selection threshold [36].

3. Results

3.1. mRNA expression profiling and filtered leprosy susceptibility gene set

We screened the mRNA expression changes by using a skin microarray data (16487 genes) of 76 individuals (GSE74481) available in NCBI GEO [39]. At the experiment-wide significance level (P -value $< 5.0 \times 10^{-6}$), there were 2134 genes differentially expressed in PB or MB patients. When we restricted the analysis to 227 leprosy-associated genes in the preliminary gene set, 123 genes were found to be differentially expressed in patient skin lesions (Table 1) and were subjected to following analyses.

3.2. GO terms enrichment

We performed the GO enrichment analyses based on the terms of BP, CC, and MF for the 123 leprosy susceptibility genes using DAVID [31], to understand the potential biological implication

behind this list of genes. For GO term BP, we got 511 terms in total, with 82 terms having a false discovery rate (FDR) < 0.05 (Supplementary Table S1). The top 10 terms were involved in activation and regulation of immune response and inflammatory response (Table 2). For GO term CC, we got 34 terms in total (Supplementary Table S1), with 13 terms having a FDR < 0.05 (Table 2). The top significant terms included extracellular space, plasma membrane, and MHC protein complex. For MF terms, we got 56 terms in total, with 7 terms having a FDR < 0.05 . The top significant terms were “MHC class II receptor activity” and “NF- κ B binding” (Supplementary Table S1).

For pathway analysis, the 123 leprosy associated genes were enriched in 21 KEGG (Kyoto Encyclopedia of Genes and Genomes: <http://www.genome.jp/kegg/>) pathways, with 11 pathways having a FDR < 0.05 (Table 2). The top pathways were associated to autoimmune disorders (e.g., allograft rejection, type I diabetes mellitus, and systemic lupus erythematosus) (Supplementary Table S1).

3.3. Cross-disorder feature

We performed a cross-disorder analysis to test whether the 123 leprosy associated genes were leprosy-specific or common for other infectious and/or immune diseases (Fig. 2 and Supplementary Table S2). A total of 85 diseases or disease-related phenotypes showed a significant enrichment of the leprosy related genes (FDR < 0.05). Typical autoimmune diseases, such as type I diabetes (enrichment $P = 1.89 \times 10^{-13}$), multiple sclerosis (enrichment $P = 7.44 \times 10^{-13}$), and systemic lupus erythematosus (enrichment $P = 3.52 \times 10^{-12}$), and well-studied infectious diseases, e.g., HIV

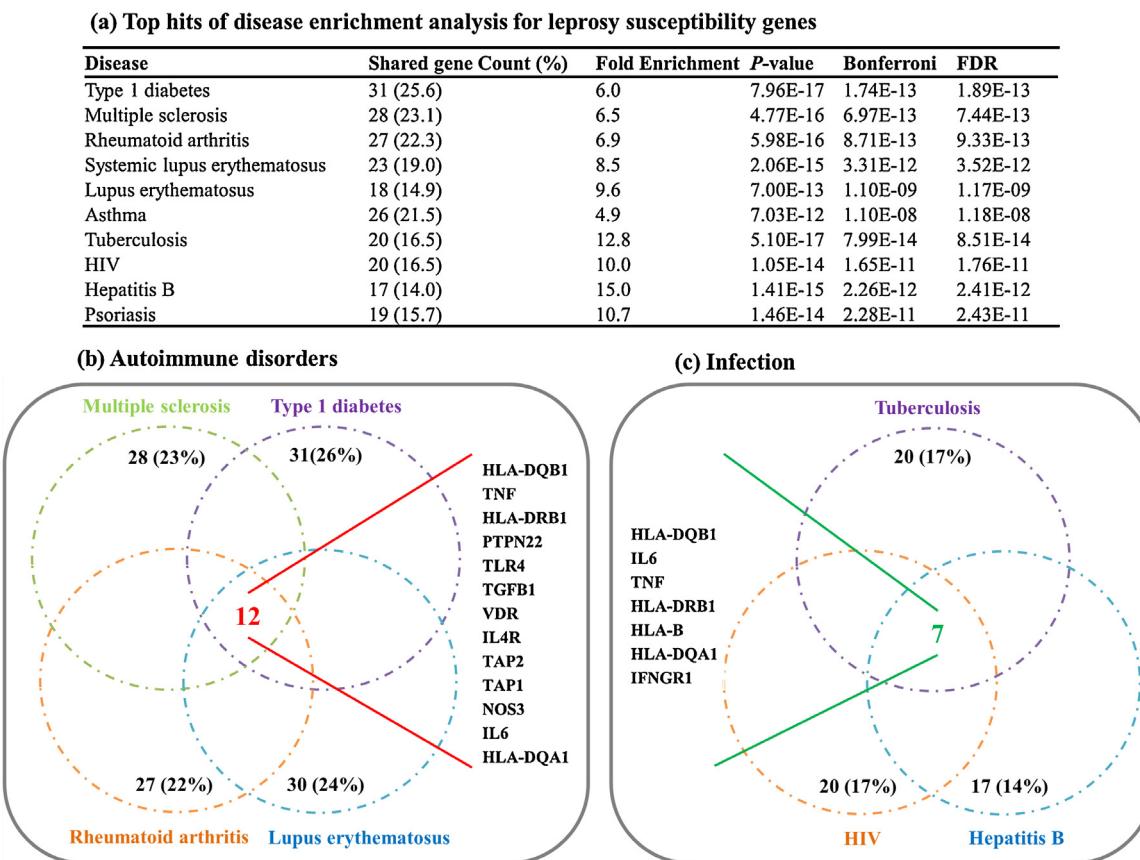

Fig. 2. Cross-disorder analysis showing that leprosy shared similar genetic risk factors with other autoimmune diseases. The list of leprosy associated genes were screened in the disease association dataset (Genetic Association DB Disease: <http://geneticassociationdb.nih.gov/>) using DAVID [31]. Typical autoimmune diseases and well-studied infectious diseases showed the largest enrichment of leprosy associated genes (a). There are 13 genes shared by leprosy and four typical autoimmune diseases (b) and 7 genes shared by leprosy and typical infectious diseases (c).

hsa05416:Viral myocarditis	3 (23.1)	19.5	0.008	0.288	7.204

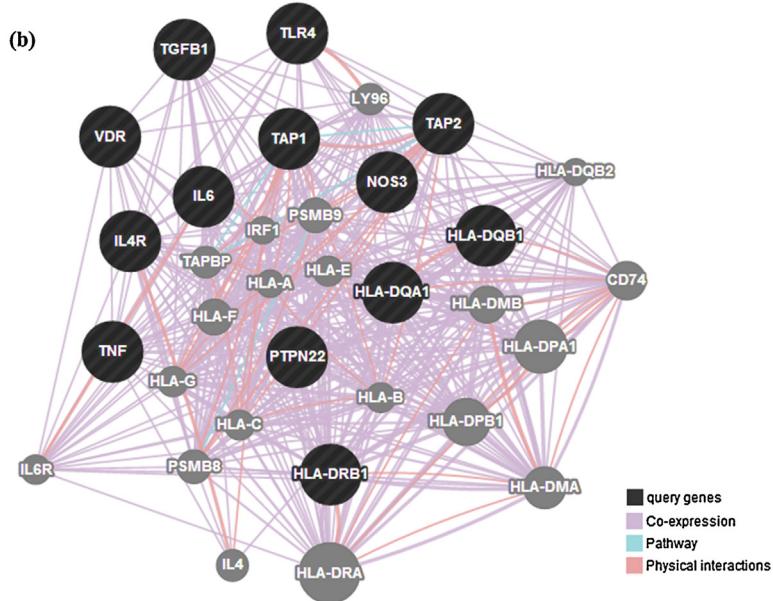

Fig. 3. Protein–protein interaction (PPI), co-expression network and enriched pathways of the 13 genes shared by leprosy and autoimmune diseases. KEGG pathway enrichment analysis (a) was performed by using DAVID [31]. PPI and co-expression network analyses (b) were performed by using the GeneMANIA prediction server (<http://www.genemania.org/>) [35].

infection (enrichment $P=1.76 \times 10^{-11}$) and tuberculosis (enrichment $P=5.81 \times 10^{-14}$), showed the largest enrichment of leprosy risk genes (Fig. 2 and Supplementary Table S2). In particular, 13 out of the 123 leprosy-associated genes were shared by leprosy and four other typical autoimmune diseases (multiple sclerosis, type 1 diabetes, rheumatoid arthritis, and lupus erythematosus) (Fig. 2). The leprosy shared autoimmune genes were also enriched in other typical autoimmune reactions such as graft-versus-host disease and allograft rejection, and in “antigen processing and presentation” and “IgA production” pathways (Fig. 3a). Comparatively, only 7 genes were shared by leprosy and the typical infectious diseases. This observation showed that leprosy shared similar genetic risk factors with other autoimmune diseases.

As the majority of the leprosy candidate genes in previous case-control studies were chosen among immune-associated genes, we need to surpass the argument in a circle through a bottom-up strategy. Therefore, we set all 2134 differently expressed ($P<5.0 \times 10^{-6}$) genes in leprosy skin tissues as another gene set for enrichment analysis. Analysis of this enlarged bottom-up gene set showed a similar pattern as the above results (Table 3).

3.4. Interaction network

We performed the PPI and co-expression network analyses to detect whether the 13 autoimmune genes shared by leprosy and other autoimmune diseases would constitute a network

underlying the regulation of immune response during leprosy onset. As expected, these genes/proteins were involved in one interaction network, with HLA-DQA1, HLA-DQB1, VDR, TNF, and TGFBI being the central nodes (Fig. 3b). It should be mentioned that the important role of TNF and VDR had been also confirmed by previous microRNA studies [30,41]. This observation indicates a common and synergistic effect of these leprosy risk genes in host immune response.

3.5. Positive selection of the leprosy susceptibility genes

M. leprae lost nearly half of its coding genes during the long evolutionary process of interaction with the host [42]. Previous studies have shown that development of leprosy is determined by host genetic background [2]. It is reasonable to speculate that leprosy associated genes may be shaped and retained in populations by positive selection. To test this speculation, we investigated the positive selection effect on these leprosy-related genes. We used an integrated method CMS [36], a tool for identifying regions that are under positive selection in the genome, and took advantage of the available data from the 1000 Genomes project (www.1000genomes.org/) [40]. We observed 18 positively selected genes in Europeans, 14 positively selected genes in East Asians, and 8 positively selected genes in Africans, respectively (Supplementary Table S3). Compared with Africans, Europeans had a significantly increased number of positively selected leprosy risk

^a The percentage is defined by the number of gene count for each terms divided by 2134 genes differentially expressed in PB or MB patients.

genes ($P=0.027$). Among these positively selected genes, *TLR1* had been previously shown to be under selection caused by *M. leprae* or other pathogens that could be recognized by *TLR1* and its co-receptors [8]. Therefore, our current analyses provided a bird view for the natural selection imprints on leprosy associated genes and added more support to the notion that the genetic basis of leprosy might be shaped by population evolutionary history.

4. Discussion

Leprosy has complex clinical features [1]. Little differences have been observed among different *M. leprae* strains across the world [6,42,43] and the diversified clinical symptoms are highly determined by host immune status and genetic background [2]. Moreover, less than 10% of people in contact with *M. leprae* would develop the disease [44,45], suggesting strong effects of host genetic background and environmental factors (e.g., nutrition). Previous studies have identified numerous leprosy risk alleles [19,20,27,46–49]. In this study, we retrieved all reported leprosy-related genes (227 genes) and performed integrated analyses, to obtain an overview of the genetic and immune basis of leprosy. After having filtered these 227 genes by referring to the mRNA expression changes in leprosy skin lesions, we got a list of 123 leprosy associated genes with evidence at both the genetic association and differential expression levels (Table 1), providing an updated preliminary gene set for further screening, fine-mapping, and functional studies. We observed no significant *M. leprae*-infection-specific signal in our results. However, we found that leprosy susceptibility genes were enriched in activation and regulation of immune response, including innate and adaptive immune response, and inflammatory response (Fig. 2). Biological

processes involving interleukins, interferons, pattern recognition receptors, and components of the complement system play essential and extensive roles in host immune responses against pathogens [11]. Intriguingly, the mRNA expression pattern of these susceptibility genes was similar between leprosy patients with different subtypes (Table 1), suggesting that these leprosy risk genes might represent a common immune and genetic profile for leprosy *per se*.

The list of leprosy susceptibility genes was largely shared by typical autoimmune diseases such as lupus erythematosus, type I diabetes, and arthritis (Figs. 2 and 3). This observation suggested that similar pathways might be affected in leprosy and autoimmune diseases. Note that *M. leprae* could be latent for many years before the clinical manifestations. In our pathway analysis, we found that the leprosy-shared autoimmune genes were enriched in other typical autoimmune reactions such as graft-versus-host disease and allograft rejection, the “antigen processing and presentation” and “IgA production” pathways (Fig. 3). On this point, we suggested that leprosy might be a kind of autoimmune disease. Interestingly, the very recent GWAS follow-up study [48] also indicated an autoimmune profile of leprosy susceptibility, adding robust support to our hypothesis.

It should be mentioned that the most shared risk genes for leprosy distilled from the cross-disorder analysis were *TNF*, *HLA-DRB1*, *HLA-DQB1*, *IL10*, *IL6*, *HLA-DQA1*, and *IFNG* (Supplementary Table S2). It is not unexpected that *HLA* genes have a very large effect because the *HLA* region is highly associated with multiple diseases as revealed by GWASs (cf. the NHGRI GWAS Catalog: <http://www.genome.gov/gwastudies/>). Genes *TNF*, *IFNG*, *IL6*, *IL10*, *NOD2*, *TLR4*, *SLC11A1*, *RIPK2*, and *BCL10* contributed the lead signal for enrichment of BP terms (Supplementary Table S1). Four genes,

TNF, *IFNG*, *IL6*, and *IL10*, which contributed most of the signals in both cross-disorder analysis and term enrichment, play an essential role in related diseases and are worthy of attention. Five genes (*NOD2*, *TLR4*, *SLC11A1*, *RIPK2*, and *BCL10*), especially *RIPK2* and *BCL10*, showed only the lead signal in BP term enrichment for leprosy but no signal in cross-disorders. *NOD2*, *RIPK2*, *TLR4*, *TLR1*, *TLR2*, and *TIRAP* were positively selected among populations (Supplementary Table S3). These leprosy associated genes might be driven by co-evolution against *M. leprae*. In addition, our analyses showed that Europeans have a significantly increased number of positively selected leprosy risk genes compared with Africans. This pattern may be caused by historical pandemics [50,51]. Interaction of evolutionary selection driven genetic background, and host immune status and environments might jointly promote the susceptibility and development of leprosy.

Why there is a common autoimmune profile of leprosy and other infectious diseases? Does this mean a universal therapy to target all these related diseases? Or can we speculate an immune nature of leprosy and related diseases, rather than disorder-specific pathology? Apparently, more assays shall be carried out to answer these questions. Nonetheless, it seems that susceptibility to leprosy or development of the disease is only a matter of defect or over-activation of host immunity. Genetic studies aiming at identifying leprosy-specific risk factors may be questionable.

In summary, the current study revealed the hub genes that were located in the center of leprosy genetic network through a comprehensive integration analysis, providing an insight into immune and genetic factors contributing to leprosy. The results also offered thoughts for further fine-mapping and functional investigation. Nevertheless, there are limitations of the current study because of the paucity of information on leprosy. Moreover, conclusions revealed by our integrative analyses were heavily dependent on limited number of reported susceptibility genes, which might show population specific association pattern. The causality of these genes in leprosy remains undefined. The overall profile revealed by this study needs further validation in the future.

Table S3. Positively selected leprosy susceptibility genes among populations

Population	YRI	CEU	CHB+JPT
Number of positively selected genes	8	18	14
<i>TLR1</i>	NO	YES	NO
<i>NOD2</i>	NO	YES	NO
<i>TLR2</i>	YES	NO	NO
<i>TLR4</i>	NO	NO	YES
<i>VDR</i>	YES	NO	NO
<i>MBL2</i>	YES	NO	NO
<i>RIPK2</i>	NO	YES	YES
<i>LACC1</i>	NO	YES	NO
<i>PARK2</i>	NO	YES	YES
<i>CCDC122</i>	NO	YES	NO
<i>COL3A1</i>	NO	NO	YES
<i>TIRAP</i>	NO	NO	YES
<i>HLA-DRB1</i>	NO	YES	NO
<i>PACRG</i>	NO	YES	NO
<i>HLA-DQB1</i>	NO	YES	NO
<i>HLA-DQA1</i>	NO	YES	NO
<i>CCL5</i>	NO	YES	NO
<i>LAMA2</i>	NO	NO	YES
<i>TNFSF8</i>	YES	NO	NO
<i>KIR2DL1</i>	NO	NO	YES
<i>CUBN</i>	YES	YES	YES
<i>NEBL</i>	NO	YES	NO
<i>MASP2</i>	YES	NO	YES
<i>IRGM</i>	YES	YES	NO
<i>NLRP1</i>	NO	YES	YES
<i>IL23R</i>	NO	NO	YES
<i>IL18RAP</i>	NO	NO	YES
<i>IL18R1</i>	NO	NO	YES
<i>IL6</i>	NO	YES	YES
<i>CFH</i>	NO	YES	NO
<i>DEC1</i>	YES	YES	NO

Note - Data of the 1000 genome project were used for the positive selection test

YRI - Yoruba in Ibadan, Nigeria [YRI]; CEU - Utah residents (CEPH) with Northern and Western European ancestry [CEU]; CHB+JPT - Han Chinese in Beijing [CHB] + Japanese in Tokyo [JPT]

Erratum

Erratum to “Integrative analyses of leprosy susceptibility genes indicate a common autoimmune profile” [J. Dermatol. Sci. 82 (2016) 18–27.]

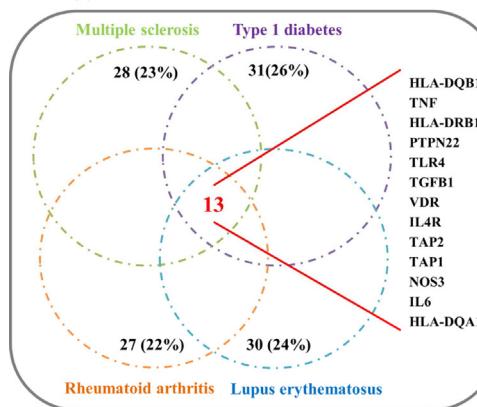

Deng-Feng Zhang^{a,c,**}, Dong Wang^a, Yu-Ye Li^b, Yong-Gang Yao^{a,c,*}^a Key Laboratory of Animal Models and Human Disease Mechanisms of the Chinese Academy of Sciences & Yunnan Province, Kunming Institute of Zoology, Kunming, Yunnan 650223, China^b Department of Dermatology, The First Affiliated Hospital of Kunming Medical University, Kunming, Yunnan 650032, China^c Kunming College of Life Science, University of Chinese Academy of Sciences, Kunming, Yunnan 650204, China

The publisher regrets that there was an error in Fig. 2 of this paper. The correct figure can be found below:

(a) Top hits of disease enrichment analysis for leprosy susceptibility genes

Disease	Shared gene Count (%)	Fold Enrichment	P-value	Bonferroni	FDR
Type 1 diabetes	31 (25.6)	6.0	7.96E-17	1.74E-13	1.89E-13
Multiple sclerosis	28 (23.1)	6.5	4.77E-16	6.97E-13	7.44E-13
Rheumatoid arthritis	27 (22.3)	6.9	5.98E-16	8.71E-13	9.33E-13
Systemic lupus erythematosus	23 (19.0)	8.5	2.06E-15	3.31E-12	3.52E-12
Lupus erythematosus	18 (14.9)	9.6	7.00E-13	1.10E-09	1.17E-09
Asthma	26 (21.5)	4.9	7.03E-12	1.10E-08	1.18E-08
Tuberculosis	20 (16.5)	12.8	5.10E-17	7.99E-14	8.51E-14
HIV	20 (16.5)	10.0	1.05E-14	1.65E-11	1.76E-11
Hepatitis B	17 (14.0)	15.0	1.41E-15	2.26E-12	2.41E-12
Psoriasis	19 (15.7)	10.7	1.46E-14	2.28E-11	2.43E-11

(b) Autoimmune disorders

(c) Infection

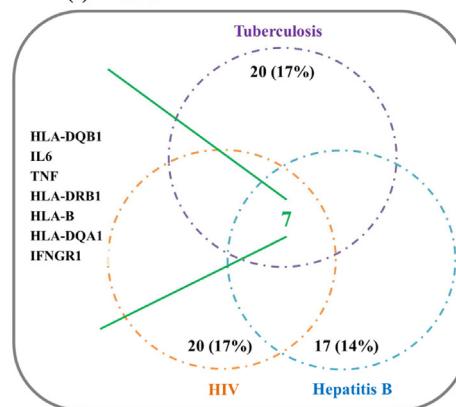

Fig. 2. Cross-disorder analysis showing that leprosy shared similar genetic risk factors with other autoimmune diseases.
